Advance Information

MICROCOMPUTER/MICROPROCESSOR (MCU/MPU)

The MC6801U4 is an 8-bit single-chip microcomputer unit (MCU) which enhances the capabilities of the MC6801 and significantly enhances the capabilities of the M6800 Family of parts. It includes an MC6801 microprocessor unit (MPU) with direct object-code compatibility and upward object-code compatibility with the MC6800. Execution times of key instructions have been improved over the MC6800 and the new instructions found on the MC6801 are included. The MCU can function as a monolithic microcomputer or can be expanded to a 64K byte address space. It is TTL compatible and requires one +5-volt power supply. On-chip resources include 4096 bytes of ROM, 192 bytes of RAM, a serial communications interface (SCI), parallel I/O, and a 16-bit six-function programmable timer. The MC6803U4 can be considered an MC6801U4 operating in modes 2 or 3; i.e., those that do not use internal ROM.

- Enhanced MC6800 Instruction Set
- Upward Source and Object Code Compatibility with the MC6800 and MC6801
- Bus Compatibility with the M6800 Family
- 8x8 Multiply Instruction
- Single-Chip or Expanded Operation to 64K Byte Address Space
- Internal Clock Generator with Divide-by-Four Output
- Serial Communications Interface (SCI)
- 16-Bit Six-Function Programmable Timer
- Three Output Compare Functions
- Two Input Capture Functions
- Counter Alternate Address
- 4096 Bytes of ROM (MC6801U4)
- 192 Bytes of RAM
- 32 Bytes of RAM Retainable During Power Down
- 29 Parallel I/O and Two Handshake Control Lines
- $\overline{\text{NMI}}$ Inhibited Until Stack Load
- -40°C to 85°C Temperature Range

Operating Temperature Range MC6801U4, MC6803U4 MC6801U4C, MC6803U4C	T_A	T_H to T_L -0 to 70 -40 to 85	°C
Storage Temperature Range	T_{stg}	-55 to +150	°C

THERMAL CHARACTERISTICS

Characteristic	Symbol	Value	Rating
Thermal Resistance Plastic Ceramic	θ_{JA}	50 50	°C/W

This device contains circuitry to protect the inputs against damage due to high static voltages or electric fields; however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation it is recommended that V_{in} and V_{out} be constrained to the range $V_{SS} \leq (V_{in} \text{ or } V_{out}) \leq V_{CC}$. Input protection is enhanced by connecting unused inputs to either V_{DD} or V_{SS} .

POWER CONSIDERATIONS

The average chip-junction temperature, T_J , in °C can be obtained from:

$$T_J = T_A + (P_D \cdot \theta_{JA}) \quad (1)$$

Where:

T_A ≡ Ambient Temperature, °C

θ_{JA} ≡ Package Thermal Resistance, Junction-to-Ambient, °C/W

P_D ≡ $P_{INT} + P_{PORT}$

P_{INT} ≡ $I_{CC} \times V_{CC}$, Watts — Chip Internal Power

P_{PORT} ≡ Port Power Dissipation, Watts — User Determined

For most applications $P_{PORT} \ll P_{INT}$ and can be neglected. P_{PORT} may become significant if the device is configured to drive Darlington bases or sink LED loads.

An approximate relationship between P_D and T_J (if P_{PORT} is neglected) is:

$$P_D = K + (T_J + 273^\circ\text{C}) \quad (2)$$

Solving equations 1 and 2 for K gives:

$$K = P_D \cdot (T_A + 273^\circ\text{C}) + \theta_{JA} \cdot P_D^2 \quad (3)$$

Where K is a constant pertaining to the particular part. K can be determined from equation 3 by measuring P_D (at equilibrium) for a known T_A . Using this value of K, the values of P_D and T_J can be obtained by solving equations (1) and (2) iteratively for any value of T_A .

CONTROL TIMING ($V_{CC} = 5.0 \text{ V} \pm 5\%$, $V_{SS} = 0$, $T_A = 0$ to 70°C)

FIGURE 7 – BUS TIMING

NOTES:

1. Voltage levels shown are $V_L \leq 0.5 V$, $V_H \geq 2.4 V$, unless otherwise specified.
2. Measurement points shown are 0.8 V and 2.0 V, unless otherwise specified.
3. Usable access time is computed by $22 + 3 - 17 + 4$.
4. Memory devices should be enabled only during E high to avoid port 3 bus contention.
5. Item 26 is different from the MC6801 but it is upward compatible.

INTRODUCTION

The MC6801U4 is an 8-bit monolithic microcomputer which can be configured to function in a wide variety of applications. The facility which provides this extraordinary flexibility is its ability to be hardware programmed into eight different operating modes. The operating mode controls the configuration of 18 of the 40 MCU pins, available on-chip resources, memory map, location (internal or external) of interrupt vectors, and type of external bus. The configuration of the remaining 22 pins is not dependent on the operating mode.

Twenty-nine pins are organized as three 8-bit ports and one 5-bit port. Each port consists of at least a data register and a write-only data direction register. The data direction register is used to define whether corresponding bits in the data register are configured as an input (clear) or output (set).

The term "port" by itself refers to all of the hardware associated with the port. When the port is used as a "data port" or "I/O port," it is controlled by the port data direction register and the programmer has direct access to the port pins using the port data register. Port pins are labeled as Pij where i identifies one of four ports and j indicates the particular bit.

The microprocessor unit (MPU) is an enhanced MC6800 MPU with additional capabilities and greater throughput. It is upward source and object code compatible with the MC6800 and the MC6801. The programming model is depicted in Figure 8 where accumulator D is a concatenation of accumulators A and B. A list of new operations added to the MC6800 instruction set are shown in Table 1.

The MC6803U4 can be considered an MC6801U4 that operates in modes 2 and 3 only.

FIGURE 8 — PROGRAMMING MODEL

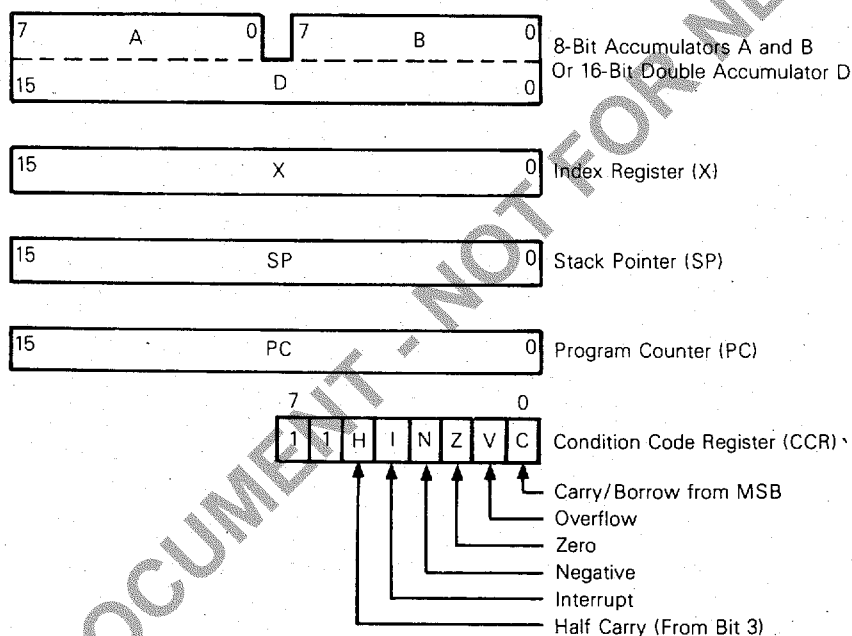

TABLE 1 — NEW INSTRUCTIONS

Instruction	Description
ABX	Unsigned addition of accumulator B to index register
ADDD	Adds (without carry) the double accumulator to memory and leaves the sum in the double accumulator
ASLD or LSLD	Shifts the double accumulator left (towards MSB) one bit, the LSB is cleared, and the MSB is shifted into the C bit
BHS	Branch if higher or same, unsigned conditional branch (same as BCC)
BLO	Branch if lower, unsigned conditional branch (same as BCS)
BRN	Branch never
JSR	Additional addressing mode direct
LDD	Loads double accumulator from memory
LSL	Shifts memory or accumulator left (towards MSB) one bit, the LSB is cleared, and the MSB is shifted into the C bit (same as ASL)
LSRD	Shifts the double accumulator right (towards LSB) one bit, the MSB is cleared, and the LSB is shifted into the C bit
MUL	Unsigned multiply, multiplies the two accumulators and leaves the product in the double accumulator
PSHX	Pushes the index register to stack
PULX	Pulls the index register from stack
STD	Stores the double accumulator to memory
SUBD	Subtracts memory from the double accumulator and leaves the difference in the double accumulator
CPX	Internal processing modified to permit its use with any conditional branch instruction

OPERATING MODES

The MC6801U4 provides seven different operating modes (modes 0 through 3 and 5 through 7) and the MC6803U4 provides two operating modes (modes 2 and 3). The operating modes are hardware selectable and determine the device memory map, the configuration of port 3, port 4, SC1, SC2, and the physical location of the interrupt vectors.

FUNDAMENTAL MODES

The seven operating modes (0-3, 5-7) can be grouped into three fundamental modes which refer to the type of bus it supports: single chip, expanded non-multiplexed, and ex-

panded multiplexed. Single chip is mode 7, expanded non-multiplexed is mode 5, and the remaining 5 are expanded multiplexed modes. Table 2 summarizes the characteristics of the operating modes.

MC6801U4 SINGLE-CHIP MODE (7) — In the single-chip mode, the four MCU ports are configured as parallel input/output data ports, as shown in Figure 9. The MCU functions as a monolithic microcomputer in this mode without external address or data buses. A maximum of 29 I/O lines and two port 3 control lines are provided. Peripherals or another MCU can be interfaced to port 3 in a loosely coupled dual-processor configuration, as shown in Figure 10.

TABLE 2 — SUMMARY OF MC6801U4/MC6803U4 OPERATING MODES

Single-Chip (Mode 7)

192 bytes of RAM, 4096 bytes of ROM
Port 3 is a parallel I/O port with two control lines
Port 4 is a parallel I/O port

Expanded Non-Multiplexed (Mode 5)

192 bytes of RAM, 4096 bytes of ROM
256 bytes of external memory space
Port 3 is an 8-bit data bus
Port 4 is an input port/address bus

Expanded Multiplexed (Modes 0, 1, 2, 3, 6*)

Four memory space options (total 64K address space)
(1) Internal RAM and ROM with partial address bus (mode 1)
(2) Internal RAM, no ROM (mode 2)
(3) Extended addressing of internal I/O and RAM
(4) Internal RAM and ROM with partial address bus (mode 6)
Port 3 is multiplexed address/data bus
Port 4 is address bus (inputs/address in mode 6)
Test mode (mode 0):
May be used to test internal RAM and ROM
May be used to test ports 3 and 4 as I/O ports by writing into mode 7
Only modes 5, 6, and 7 can be irreversibly entered from mode 0

Resources Common to All Modes

Reserved register area
Port 1 input/output operation
Port 2 input/output operation
Timer operation
Serial communications interface operation

*The MC6803U4 operates only in modes 2 and 3.

FIGURE 9 — SINGLE-CHIP MODE

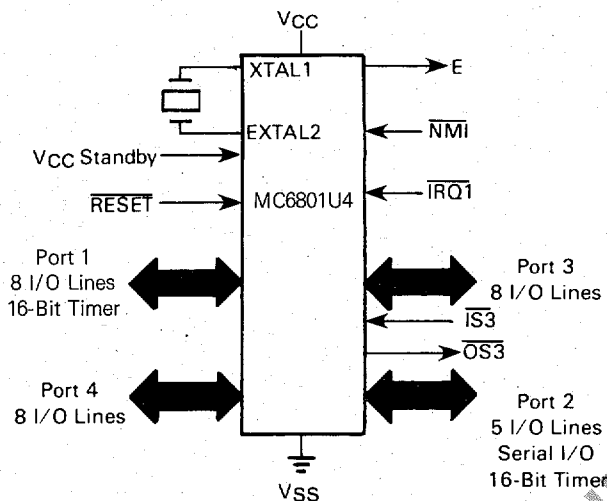

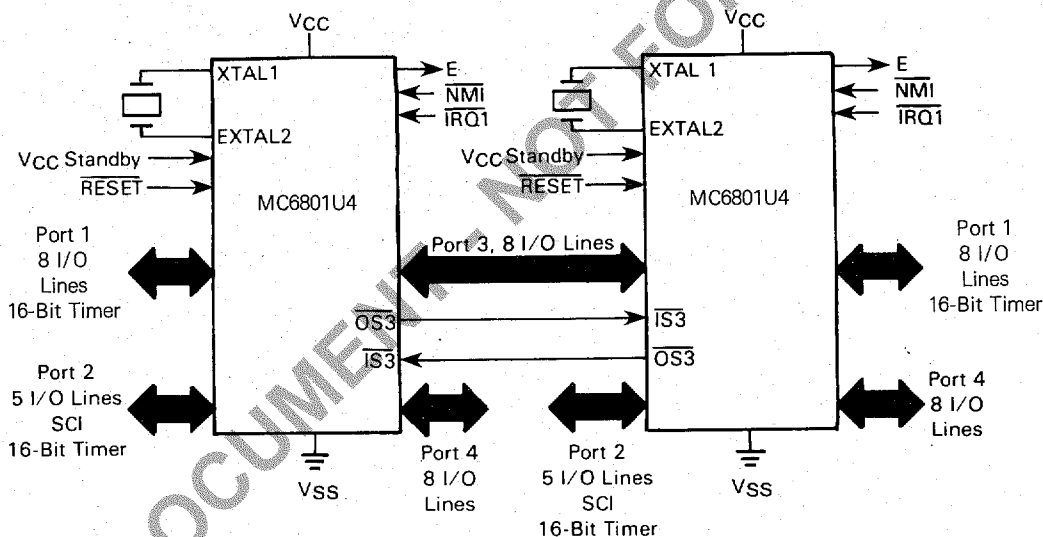

FIGURE 10 — SINGLE-CHIP DUAL PROCESSOR CONFIGURATION

MC6801U4 EXPANDED NON-MULTIPLEXED MODE (5)

— A modest amount of external memory space is provided in the expanded non-multiplexed mode while significant on-chip resources are retained. Port 3 functions as an 8-bit bidirectional data bus and port 4 is configured initially as an input data port. Any combination of the eight least significant address lines may be obtained by writing to the port 4 data direction register. Stated alternatively, any combination of A0 to A7 may be provided while retaining the remainder as input data lines. Internal pullup resistors pull the port 4 lines high until the port is configured.

Figure 11 illustrates a typical system configuration in the expanded non-multiplexed mode. The MCU interfaces directly with M6800 family parts and can access 256 bytes of external address space at \$100 through \$1FF. IOS provides an address decode of external memory (\$100-\$1FF) and can be used as a memory-page select or chip-select line.

EXPANDED MULTIPLEXED MODES (0, 1, 2, 3, 6) — A

64K byte memory space is provided in the expanded multiplexed modes. In each of the expanded multiplexed modes, port 3 functions as a time multiplexed address/data bus with address valid on the negative edge of address strobe (AS) and data valid while E is high. In modes 0, 2, and 3, port 4 provides address lines A8 to A15. In modes 1 and 6, however, port 4 initially is configured at reset as an input data port. The port 4 data direction register can then be changed to provide any combination of address lines A8 to A15. Stated alternatively, any subset of A8 to A15 can be provided while retaining the remaining port 4 lines as input data lines. Internal pullup resistors pull the port 4 lines high until software configures the port. In mode 1, the internal pullup resistors will hold the upper address lines high producing a value of \$FFXX for a reset vector. A simple method of getting the desired address lines configured as outputs is to have an external EPROM not fully decoded so it appears as

two address locations (i.e., \$FXXX and \$BXXX). Then, when the reset vector appears as \$FFFE, the EPROM will be accessed and can point to an address in the top \$100 bytes of the internal or external ROM/EPROM that will configure port 4 as desired.

In mode 0, the reset and interrupt vectors are located at \$BFF0-\$BFFF. In addition, the internal and external data buses are connected, so there must be no memory map overlap in order to avoid potential bus conflicts. By writing the PC0-PC2 bits in the port 2 data register, modes 5, 6, and 7 can be irreversibly entered from mode 0. Mode 0 is used

primarily to verify the ROM pattern and monitor the internal data bus with the automated test equipment.

Only the MC6801U4 can operate in each of the expanded multiplexed modes. The MC6803U4 operates only in modes 2 and 3.

Figure 12 depicts a typical configuration for the expanded multiplexed modes. Address strobe can be used to control a transparent D-type latch to capture addresses A0-A7, as shown in Figure 13. This allows port 3 to function as a data bus when E is high.

FIGURE 11 — EXPANDED NON-MULTIPLEXED CONFIGURATION

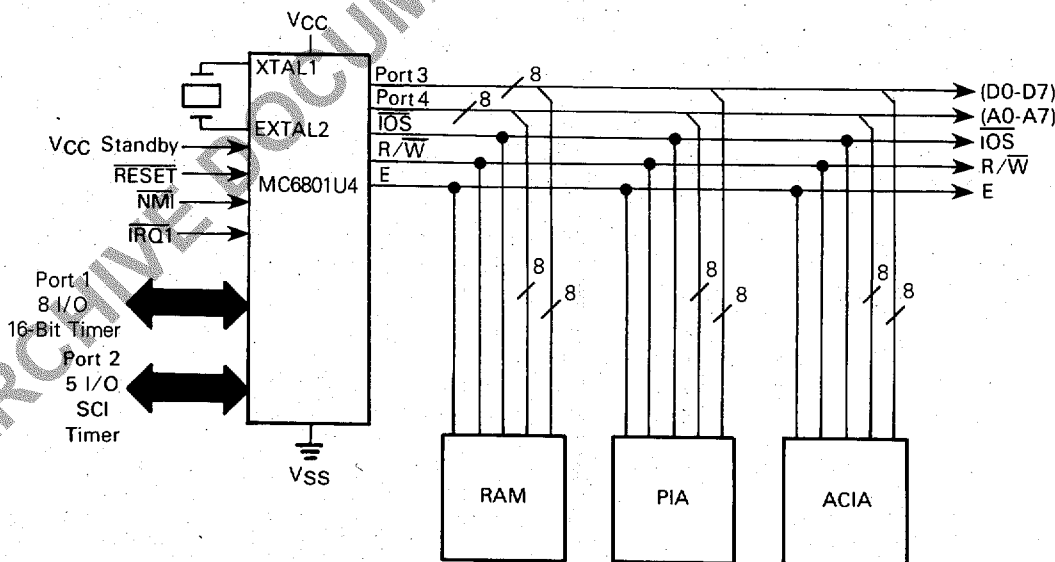

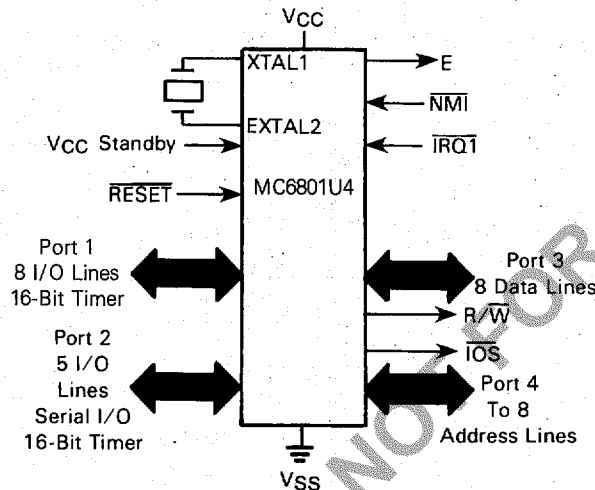

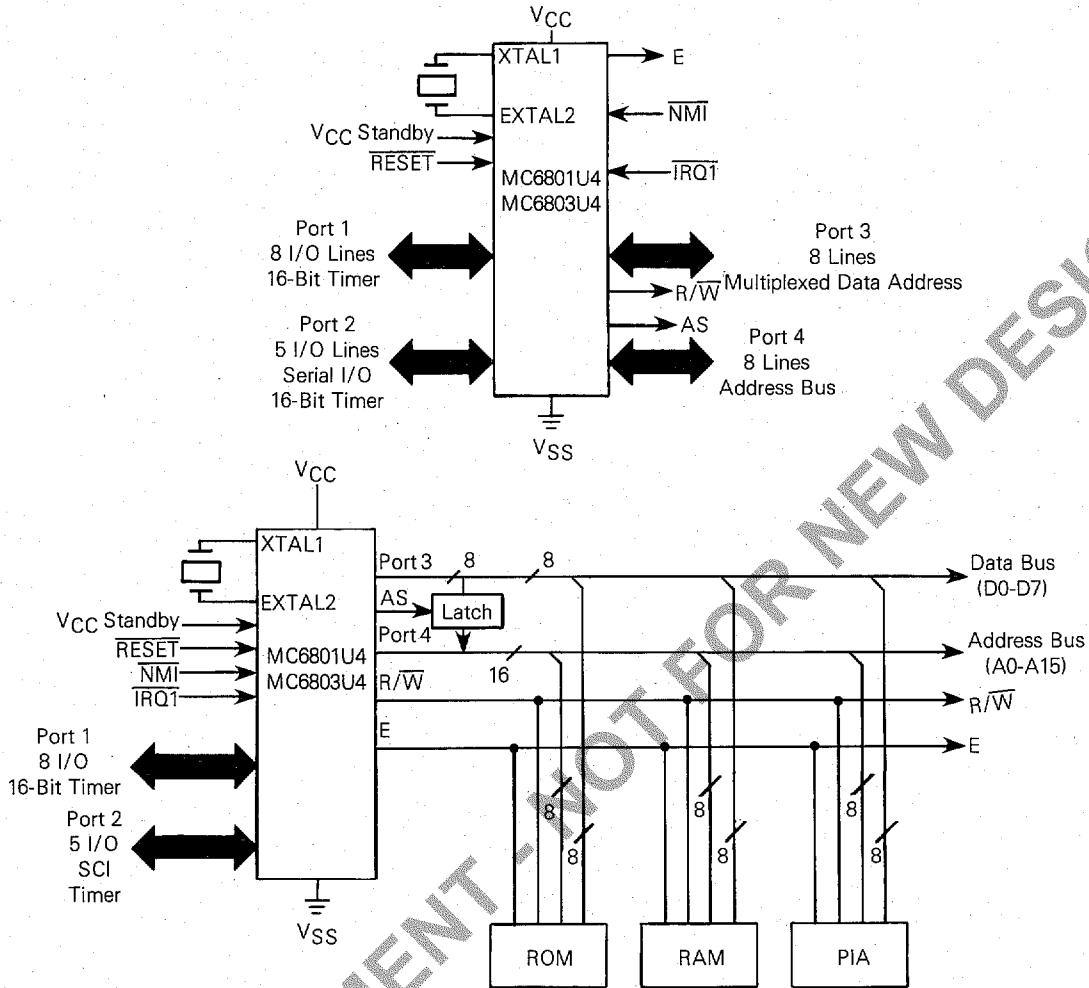

FIGURE 12 — EXPANDED MULTIPLEXED CONFIGURATION

NOTE: To avoid data bus (port 3) contention in the expanded multiplexed modes, memory devices should be enabled only during E high time.

FIGURE 13 — TYPICAL LATCH ARRANGEMENT

PROGRAMMING THE MODE

The operating mode is determined at $\overline{\text{RESET}}$ by the levels asserted on P22, P21, and P20. These levels are latched into PC2, PC1, and PC0 of the program control register on the positive edge of $\overline{\text{RESET}}$. The operating mode may be read from the port 2 data register, as shown below, and programming levels and timing must be met as shown in Figure 14. A brief outline of the operating modes is shown in Table 3.

FIGURE 14 — MODE PROGRAMMING TIMING

MODE PROGRAMMING (Refer to Figure 14)

Characteristic	Symbol	Min	Max	Unit

LEGEND

- I — Internal
- E — External
- MUX — Multiplexed
- NMUX — Non-Multiplexed
- L — Logic "0"
- H — Logic "1"

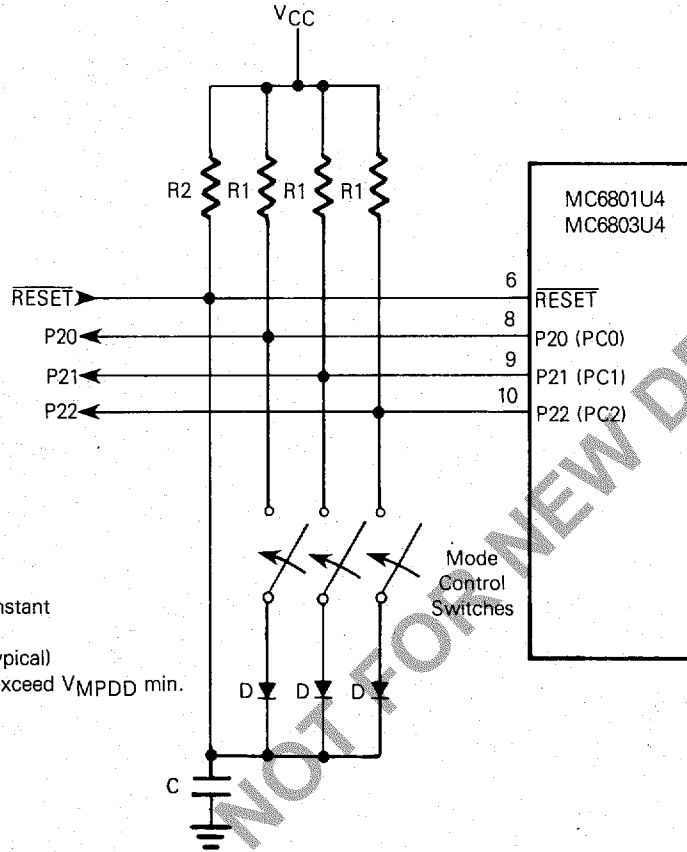

NOTES:

1. Addresses associated with ports 3 and 4 are considered external in modes 0, 1, 2, and 3.
2. Addresses associated with port 3 are considered external in modes 5 and 6.
3. Port 4 default is user data input; address output is optional by writing to port 4 data direction register.
4. Mode 4 is a non-user mode and should not be used as an operating mode.
5. Mode 3 has the internal RAM and internal registers relocated at \$D000-\$D0FF.

*The MC6803U4 operates only in modes 2 and 3.

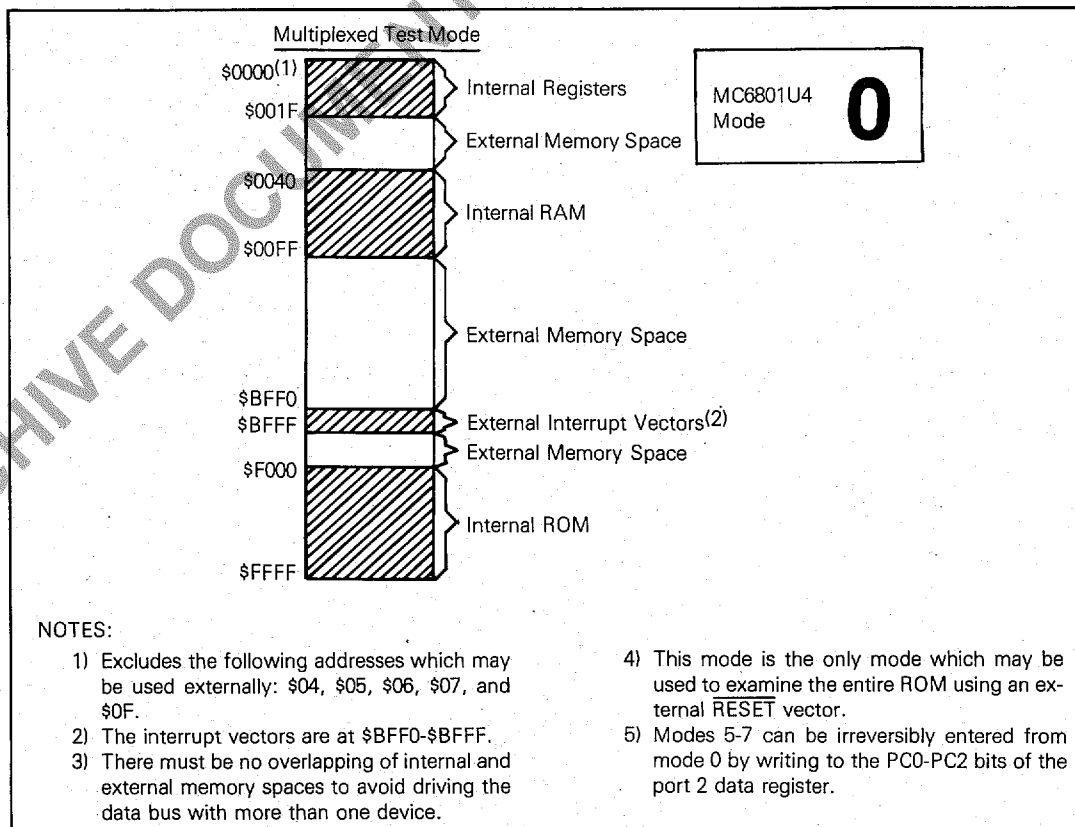

FIGURE 15 — TYPICAL MODE PROGRAMMING CIRCUIT

NOTES:

1. Mode 7 as shown
2. $R2 \cdot C =$ Reset time constant
3. $R1 = 10\text{ k}$ (typical)
4. $D = 1N914, 1N4001$ (typical)
5. Diode V_f should not exceed V_{MPDD} min.

FIGURE 16 — MC6801U4/MC6803U4 MEMORY MAPS (Sheet 1 of 4)

NOTES:

- 1) Excludes the following addresses which may be used externally: \$04, \$05, \$06, \$07, and \$0F.
- 2) The interrupt vectors are at \$BFF0-\$BFFF.
- 3) There must be no overlapping of internal and external memory spaces to avoid driving the data bus with more than one device.
- 4) This mode is the only mode which may be used to examine the entire ROM using an external RESET vector.
- 5) Modes 5-7 can be irreversibly entered from mode 0 by writing to the PC0-PC2 bits of the port 2 data register.

MC6801U4/MC6803U4 INTERRUPTS

The M6801 Family supports two types of interrupt requests: maskable and non-maskable. A non-maskable interrupt (NMI) is always recognized and acted upon at the completion of the current instruction. Maskable interrupts are controlled by the condition code register I bit and by individual enable bits. The I bit controls all maskable interrupts. Of the maskable interrupts, there are two types: $\overline{IRQ1}$ and $\overline{IRQ2}$. The programmable timer and serial communications interface use an internal $\overline{IRQ2}$ interrupt line, as shown in the block diagram. External devices and IS3 use $\overline{IRQ1}$. An $\overline{IRQ1}$ interrupt is serviced before $\overline{IRQ2}$ if both are pending.

NOTE

After reset, an \overline{NMI} will not be serviced until the first program load of the stack pointer. Any \overline{NMI} generated before this load will be remembered by the processor and serviced subsequent to the stack pointer load.

All $\overline{IRQ2}$ interrupts use hardware prioritized vectors. The single \overline{SCI} interrupt and three timer interrupts are serviced in a prioritized order and each is vectored to a separate location. All interrupt vector locations are shown in Table 5. In mode 0, reset and interrupt vectors are defined as \$BFF0-\$BFFF.

The interrupt flowchart is depicted in Figure 17 and is common to every interrupt excluding reset. During interrupt servicing, the program counter, index register, A accumulator, B accumulator, and condition code register are pushed to the stack. The I bit is set to inhibit maskable interrupts and a vector is fetched corresponding to the current highest priority interrupt. The vector is transferred to the program counter and instruction execution is resumed. Interrupt and RESET timing are illustrated in Figures 18 and 19.

TABLE 5 — MCU INTERRUPT VECTOR LOCATIONS

Mode 0		Modes 1-3, 5-7		Interrupt***
MSB	LSB	MSB	LSB	
BFFE	BFFF	FFFE	FFFF	RESET
BFFC	BFFD	FFFC	FFFD	Non-Maskable Interrupt**
BFFA	BFFB	FFFA	FFFB	Software Interrupt
BFF8	BFF9	FFF8	FFF9	Maskable Interrupt Request 1
BFF6	BFF7	FFF6	FFF7	Input Capture Flag*

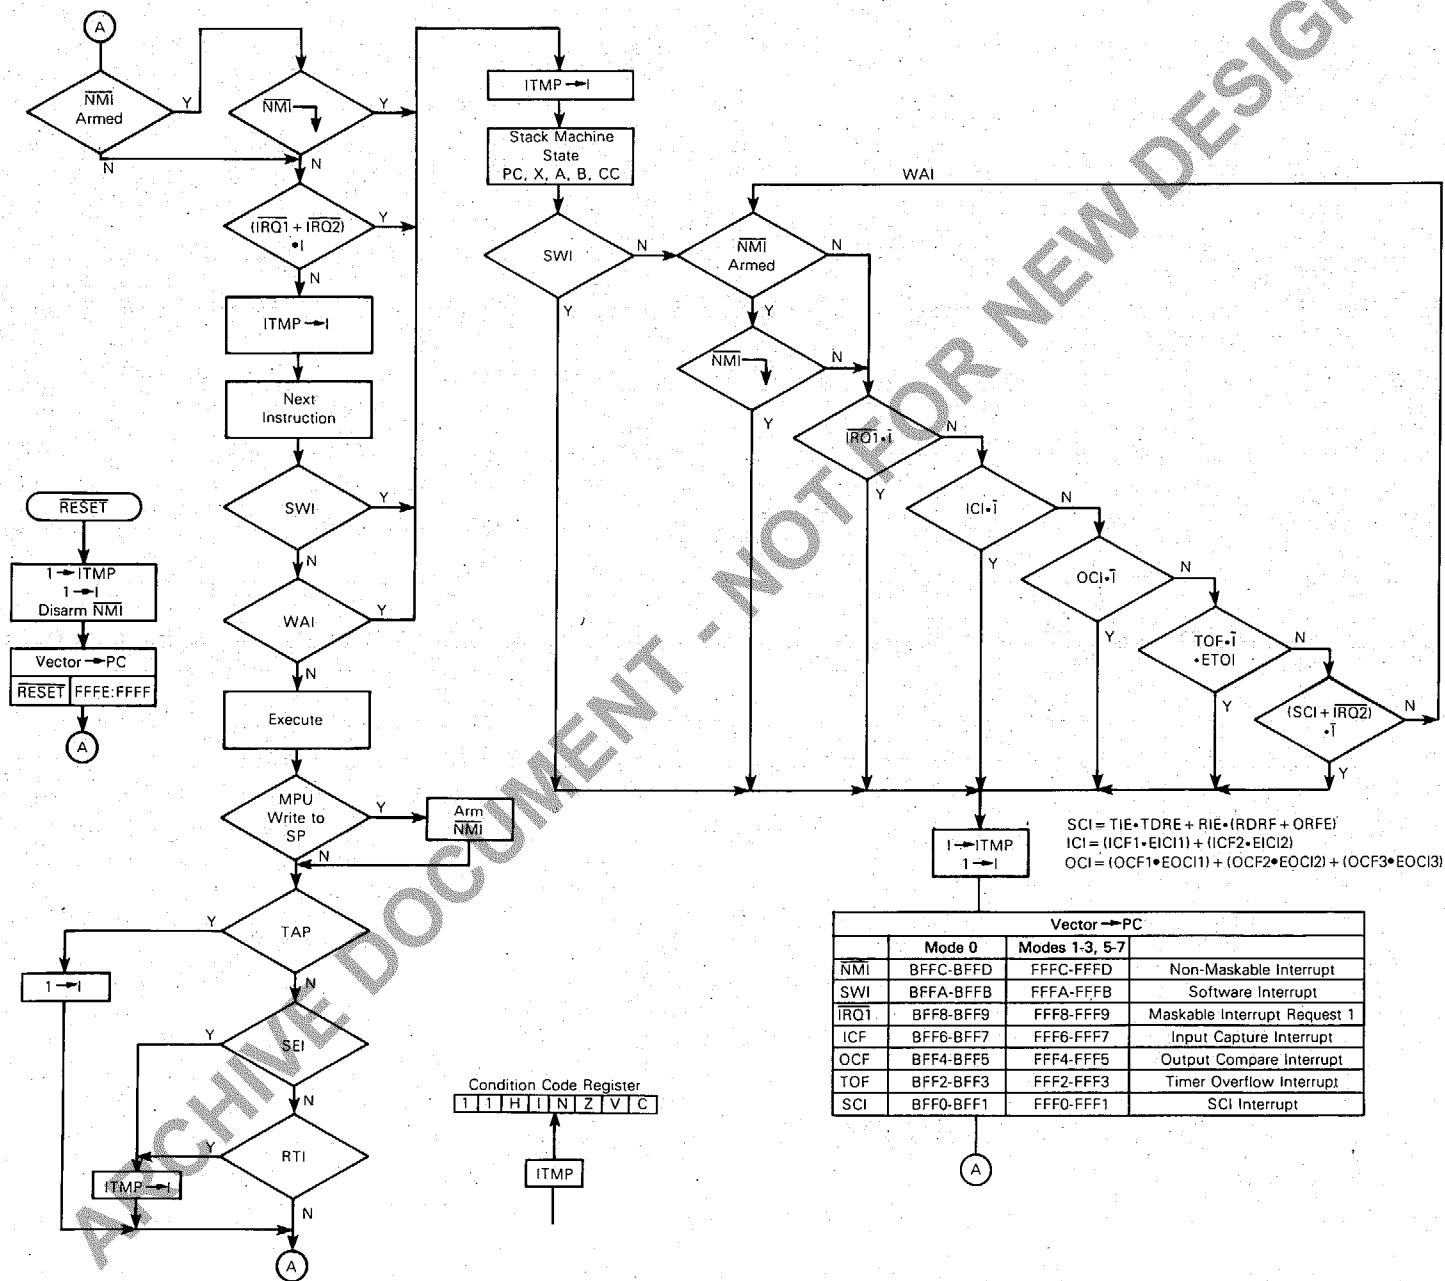

FIGURE 18 — INTERRUPT SEQUENCE

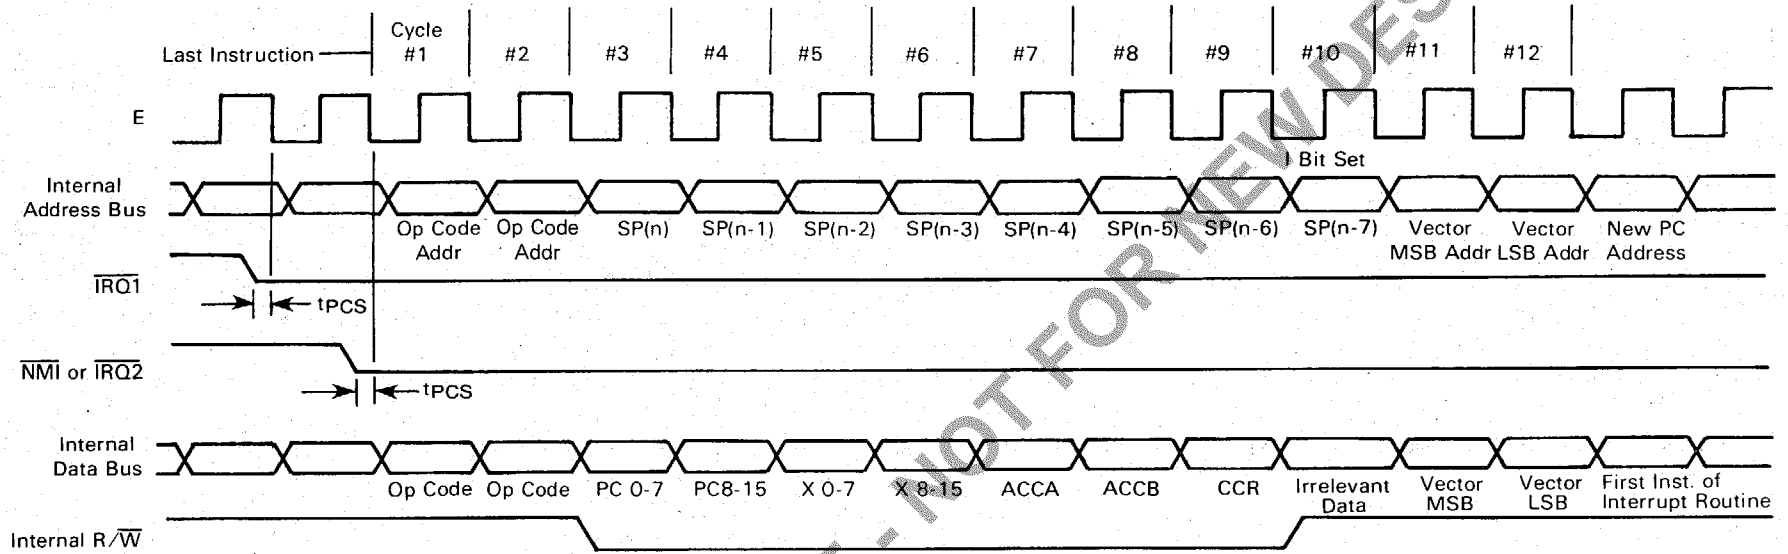

FIGURE 19 — RESET TIMING

Not Valid

FUNCTIONAL PIN DESCRIPTIONS

V_{CC} AND V_{SS}

V_{CC} and V_{SS} provide power to a large portion of the MCU. The power supply should provide +5 volts ($\pm 5\%$) to V_{CC} and V_{SS} should be tied to ground. Total power dissipation (including V_{CC} standby) will not exceed P_D milliwatts.

V_{CC} STANDBY

V_{CC} standby provides power to the standby portion (\$40 through \$5F in all modes except mode 3 which is \$D040 through \$D05F) of the RAM and the STBY PWR and RAME bits of the RAM control register. Voltage requirements depend on whether the device is in a power-up or power-down state. In the power-up state, the power supply should provide +5 volts ($\pm 5\%$) and must reach V_{SB} volts before RESET reaches 4.0 volts. During power down, V_{CC} standby must remain above V_{SB} (minimum) to sustain the standby RAM and STBY PWR bit. While in power-down operation, the standby current will not exceed I_{SB}.

It is typical to power both V_{CC} and V_{CC} standby from the same source during normal operation. A diode must be used between them to prevent supplying power to V_{CC} during power-down operation.

XTAL1 AND EXTAL 2

These two input pins interface either a crystal or TTL-compatible clock to the MCU internal clock generator. Divide-by-four circuitry is included which allows use of the inexpensive 3.58 MHz or 4.4336 MHz color burst TV crystals. A 20 pF capacitor should be tied from each crystal pin to ground to ensure reliable startup and operation. Alternatively, EXTAL2 may be driven by an external TTL-compatible clock at 4 f₀ with a duty cycle of 50% ($\pm 5\%$) with XTAL1 connected ground.

The internal oscillator is designed to interface with an AT-cut quartz crystal resonator operated in parallel resonance mode in the frequency range specified for XTAL. The crystal should be mounted as close as possible to the input pins to minimize output distortion and startup stabilization time. The MCU is compatible with most commercially available crystals. Nominal crystal parameters are shown in Figure 20.

RESET

This input is used to reset the internal state of the device and provide an orderly startup procedure. During power up, RESET must be held below 0.8 volts: (1) at least t_{RC} after V_{CC} reaches 4.75 volts in order to provide sufficient time for the clock generator to stabilize, and (2) until V_{CC} standby reaches 4.75 volts. RESET must be held low at least three E cycles if asserted during power-up operation.

E (ENABLE)

This is an output clock used primarily for bus synchronization. It is TTL compatible and is the slightly skewed divide-by-four result of the device input clock frequency. It will drive one Schottky TTL load and 90 pF, and all data given in cycles is referenced to this clock unless otherwise noted.

NMI (NON-MASKABLE INTERRUPT)

An NMI negative edge requests an MCU interrupt sequence, but the current instruction will be completed before

it responds to the request. The MCU will then begin an interrupt sequence. Finally, a vector is fetched from \$FFFC and \$FFFD (\$BFFC and \$BFFD in mode 0), transferred to the program counter, and instruction execution is resumed. NMI typically requires a 3.3 k Ω (nominal) resistor to V_{CC}. There is no internal NMI pullup resistor. NMI must be held low for at least one E cycle to be recognized under all conditions.

NOTE

After reset, an NMI will not be serviced until the first program load of the stack pointer. Any NMI generated before this load will remain pending by the processor.

IRQ1 (MASKABLE INTERRUPT REQUEST 1)

IRQ1 is a level-sensitive input which can be used to request an interrupt sequence. The MPU will complete the current instruction before it responds to the request. If the interrupt mask bit (I1 bit) in the condition code register is clear, the MCU will begin an interrupt sequence. A vector is fetched from \$FFF8 and \$FFF9 (\$BFF8 and \$BFF9 in mode 0), transferred to the program counter, and instruction execution is resumed.

IRQ1 typically requires an external 3.3 k Ω (nominal) resistor to V_{CC} for wire-OR applications. IRQ1 has no internal pullup resistor.

SC1 AND SC2 (STROBE CONTROL 1 AND 2)

The function of SC1 and SC2 depends on the operating mode. SC1 is configured as an output in all modes except single-chip mode, whereas SC2 is always an output. SC1 and SC2 can drive one Schottky load and 90 pF.

SC1 AND SC2 IN SINGLE-CHIP MODE — In single-chip mode, SC1 and SC2 are configured as an input and output, respectively, and both function as port 3 control lines. SC1 functions as IS3 and can be used to indicate that port 3 input data is ready or output data has been accepted. Three options associated with IS3 are controlled by the port 3 control and status register and are discussed in the port 3 description; refer to P30-P37 (PORT 3). If unused, IS3 can remain unconnected.

SC2 is configured as OS3 and can be used to strobe output data or acknowledge input data. It is controlled by output strobe select (OSS) in the port 3 control and status register. The strobe is generated by a read (OSS=0) or write (OSS=1) to the port 3 data register. OS3 timing is shown in Figure 3.

SC1 AND SC2 IN EXPANDED NON-MULTIPLEXED MODE — In the expanded non-multiplexed mode, both SC1 and SC2 are configured as outputs. SC1 functions as input/output select (IOS) and is asserted only when \$0100 through \$01FF is sensed on the internal address bus.

SC2 is configured as read/write and is used to control the direction of data bus transfers. An MPU read is enabled when read/write and E are high.

SC1 AND SC2 IN EXPANDED MULTIPLEXED MODE — In the expanded multiplexed modes, both SC1 and SC2 are configured as outputs. SC1 functions as address strobe and can be used to demultiplex the eight least significant addresses and the data bus. A latch controlled by address strobe captures the lower address on the negative edge, as shown in Figure 13.

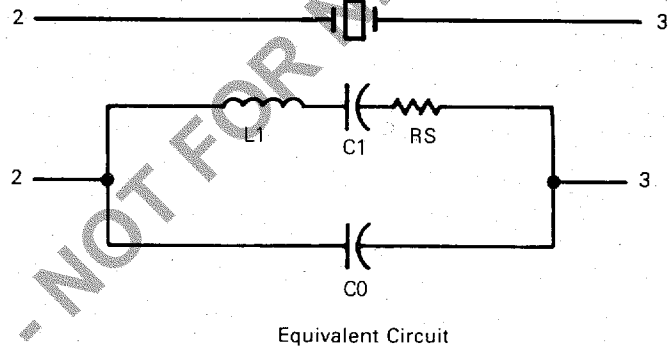

FIGURE 20 — MC6801U4/MC6803U4 FAMILY OSCILLATOR CHARACTERISTICS

(a) Nominal Recommended Crystal Parameters

Nominal Crystal Parameters*			
	3.58 MHz	4.00 MHz	5.0 MHz

Telex: 433-0067

(b) Oscillator Stabilization Time (t_{RC})

SC2 is configured as read/write and is used to control the direction of data bus transfers. An MPU read is enabled when read/write and E are high.

P10-P17 (PORT 1)

Port 1 is a mode independent 8-bit I/O and timer port. Each line can be configured as either an input or output as defined by the port 1 data direction register. Port 1 bits 0, 1, and 2 (P10, P11, and P12) can also be used to exercise one input edge function and two output compare functions of the timer. The TTL compatible three-state buffers can drive one Schottky TTL load and 30 pF, Darlington transistors, or CMOS devices using external pullup resistors. It is configured as a data input port during RESET. Unused pins can remain unconnected.

P20-P24 (PORT 2)

Port 2 is a mode-independent, 5-bit, multipurpose I/O port. The voltage levels present on P20, P21, and P22 on the rising edge of RESET determine the operating mode of the MCU. The entire port is then configured as a data input port. The port 2 lines can be selectively configured as data output lines by setting the appropriate bits in the port 2 data direction register. The port 2 data register is used to move data through the port. However, if P21 is configured as an output, it is tied to the timer output compare 1 function and cannot be used to provide output from the port 2 data register unless output enable 1 (OE1) is cleared in timer control register 1.

Port 2 can also be used to provide an interface for the serial communications interface and the timer input edge function. These configurations are described in SERIAL COMMUNICATIONS INTERFACE and PROGRAMMABLE TIMER.

The port 2 three-state TTL-compatible output buffers are capable of driving one Schottky TTL load and 30 pF, or CMOS devices using external pullup resistors.

PORT 2 DATA REGISTER

7	6	5	4	3	2	1	0	
PC2	PC1	PC0	P24	P23	P22	P21	P20	\$03

P30-P37 (PORT 3)

Port 3 can be configured as an I/O port, a bidirectional 8-bit data bus, or a multiplexed address/data bus depending on the operating mode. The TTL compatible three-state output buffers can drive one Schottky TTL load and 90 pF. Unused lines can remain unconnected.

PORT 3 IN SINGLE-CHIP MODE — Port 3 is an 8-bit I/O port in the single-chip mode with each line configured by the port 3 data direction register. There are also two lines, IS3 and OSS, which can be used to control port 3 data transfers.

Three port 3 options are controlled by the port 3 control and status register and are available only in single-chip mode: 1) port 3 input data can be latched using IS3 as a control signal, 2) OSS can be generated by either an MPU read or write to the port 3 data register, and 3) an IRQ1 interrupt can be enabled by an IS3 negative edge. Port 3 latch timing is shown in Figure 4.

PORT 3 CONTROL AND STATUS REGISTER

7	6	5	4	3	2	1	0	
IS3 Flag	IS3 IRQ1	X	OSS	Latch Enable	X	X	X	\$0F

Bits 0-2 Not used.

Bit 3 **Latch Enable** — This bit controls the input latch for port 3. If set, input data is latched by an IS3 negative edge. The latch is transparent after a read of the port 3 data register. Latch enable is cleared during reset.

Bit 4 **OSS (Output Strobe Select)** — This bit determines whether OSS will be generated by a read or write of the port 3 data register. When clear, the strobe is generated by a read; when set, it is generated by a write. OSS is cleared during reset.

Bit 5 Not used.

Bit 6 **IS3 IRQ1 Enable** — When set, an IRQ1 interrupt will be enabled whenever the IS3 flag is set; when clear, the interrupt is inhibited. This bit is cleared during reset.

Bit 7 **IS3 Flag** — This read-only status bit is set by an IS3 negative edge. It is cleared by a read of the port 3 data register or during reset.

PORT 3 IN EXPANDED NON-MULTIPLEXED MODE

Port 3 is configured as a bidirectional data bus (D7-D0) in the expanded non-multiplexed mode. The direction of data transfers is controlled by read/write (SC2). Data is clocked by E (enable).

PORT 3 IN EXPANDED MULTIPLEXED MODE — Port 3 is configured as a time multiplexed address (A7-A0) and data bus (D7-D0) in the expanded multiplexed mode where address strobe (AS) can be used to demultiplex the two buses. Port 3 is held in a high-impedance state between valid address and data to prevent bus conflicts.

P40-P47 (PORT 4)

Port 4 is configured as an 8-bit I/O port, as address outputs, or as data inputs depending on the operating mode. Port 4 can drive one Schottky TTL load and 90 pF, and is the only port with internal pullup resistors. Unused lines can remain unconnected.

PORT 4 IN SINGLE-CHIP MODE — In single-chip mode, port 4 functions as an 8-bit I/O port with each line configured by the port 4 data direction register. Internal pullup resistors allow the port to directly interface with CMOS at 5-volt levels. External pullup resistors to more than 5 volts, however, cannot be used.

PORT 4 IN EXPANDED NON-MULTIPLEXED MODE — Port 4 is configured from reset as an 8-bit input port where the port 4 data direction register can be written to provide any or all of eight address lines A0 to A7. Internal pullup resistors pull the lines high until the port 4 data direction register is configured.

PORT 4 IN EXPANDED MULTIPLEXED MODE — In all expanded multiplexed modes except modes 1 and 6, port 4 functions as half of the address bus and provides A8 to A15. In modes 1 and 6, the port is configured from reset as an 8-bit parallel input port where the port 4 data direction register can be written to provide any or all of upper address lines A8 to A15. Internal pullup resistors pull the lines high until the port 4 data direction register is configured where bit 0 controls A8.

RESIDENT MEMORY

The MC6801U4 provides 4096 bytes of on-chip ROM and 192 bytes of on-chip RAM.

Thirty-two bytes of the RAM are powered through the V_{CC} standby pin and are maintainable during V_{CC} power down. This standby portion of the RAM consists of 32 bytes located from \$40 through \$5F in all modes except mode 3 which is \$D040 through \$D05F.

Power must be supplied to V_{CC} standby if the internal RAM is to be used regardless of whether standby power operation is anticipated.

The RAM is controlled by the RAM control register.

RAM CONTROL REGISTER (\$14)

The RAM control register includes two bits which can be used to control RAM accesses and determine the adequacy of the standby power source during power-down operation. It is intended that RAME be cleared and STBY PWR be set as part of a power-down procedure.

RAM CONTROL REGISTER

7	6	5	4	3	2	1	0	
STBY PWR	RAME	X	X	X	X	X	X	\$14

Bits 0-5 Not used.

Bit 6 RAM Enable — This read/write bit can be used to remove the entire RAM from the internal memory map. RAME is set (enabled) during reset provided standby power is available on the positive edge of RESET. If RAME is clear, any access to a RAM address is external. If RAME is set, the RAM is included in the internal map.

Bit 7 Standby Power — This bit is a read/write status bit which when cleared indicates that V_{CC} standby has decreased sufficiently below V_{SBB} (minimum) to make data in the standby RAM suspect. It can be set only by software and is not affected during reset.

PROGRAMMABLE TIMER

The programmable timer can be used to perform measurements on two separate input waveforms while independently generating three output waveforms. Pulse widths can vary from several microseconds to many seconds. A block diagram of the timer is shown in Figure 21.

COUNTER (\$09:0A), (\$15, \$16)

The key timer element is a 16-bit free-running counter

which is incremented by E (enable). It is cleared during reset and is read-only with one exception: in mode 0 a write to the counter (\$09) will configure it to \$FFF8. This feature, intended for testing, can disturb serial operations because the counter provides the SCI internal bit rate clock. The TOF is set whenever the counter contains all ones. If ETOI is set, an interrupt will occur when the TOF is set. The counter may also be read as \$15 and \$16 to avoid inadvertently clearing the TOF.

OUTPUT COMPARE REGISTERS (\$0B:0C), (\$1A:1B), (\$1C:1D)

The three output compare registers are 16-bit read/write registers, each used to control an output waveform or provide an arbitrary time-out flag. They are compared with the free-running counter during the negative half of each E cycle. When a match occurs, the corresponding output compare flag (OCF) is set and the corresponding output level (OLVL) is clocked to an output level register. If both the corresponding output enable bit and data direction register bit are set, the value represented in the output level register will appear on the corresponding port pin. The appropriate OLVL bit can then be changed for the next compare.

The function is inhibited for one cycle after a write to its high byte (\$0B, \$1A, or \$1C) to ensure a valid compare after a double byte write. Writes can be made to either byte of the output compare register without affecting the other byte. The OLVL value will be clocked out independently of whether the OCF had previously been cleared. The output compare registers are set to \$FFFF during reset.

INPUT CAPTURE REGISTERS (\$0D:0E), (\$1E:1F)

The two input capture registers are 16-bit read-only registers used to store the free-running counter when a "proper" input transition occurs as defined by the corresponding input edge bit (IEDG1 or IEDG2). The input pin's data direction register should be configured as an input, but the edge detect circuit always senses P10 and P20 even when configured as an output. The counter value will be latched into the input capture registers on the second negative edge of the E clock following the transition.

An input capture can occur independently of ICF; the register always contains the most current value. Counter transfer is inhibited, however, between accesses of a double byte MPU read. The input pulse width must be at least two E cycles to ensure an input capture under all conditions.

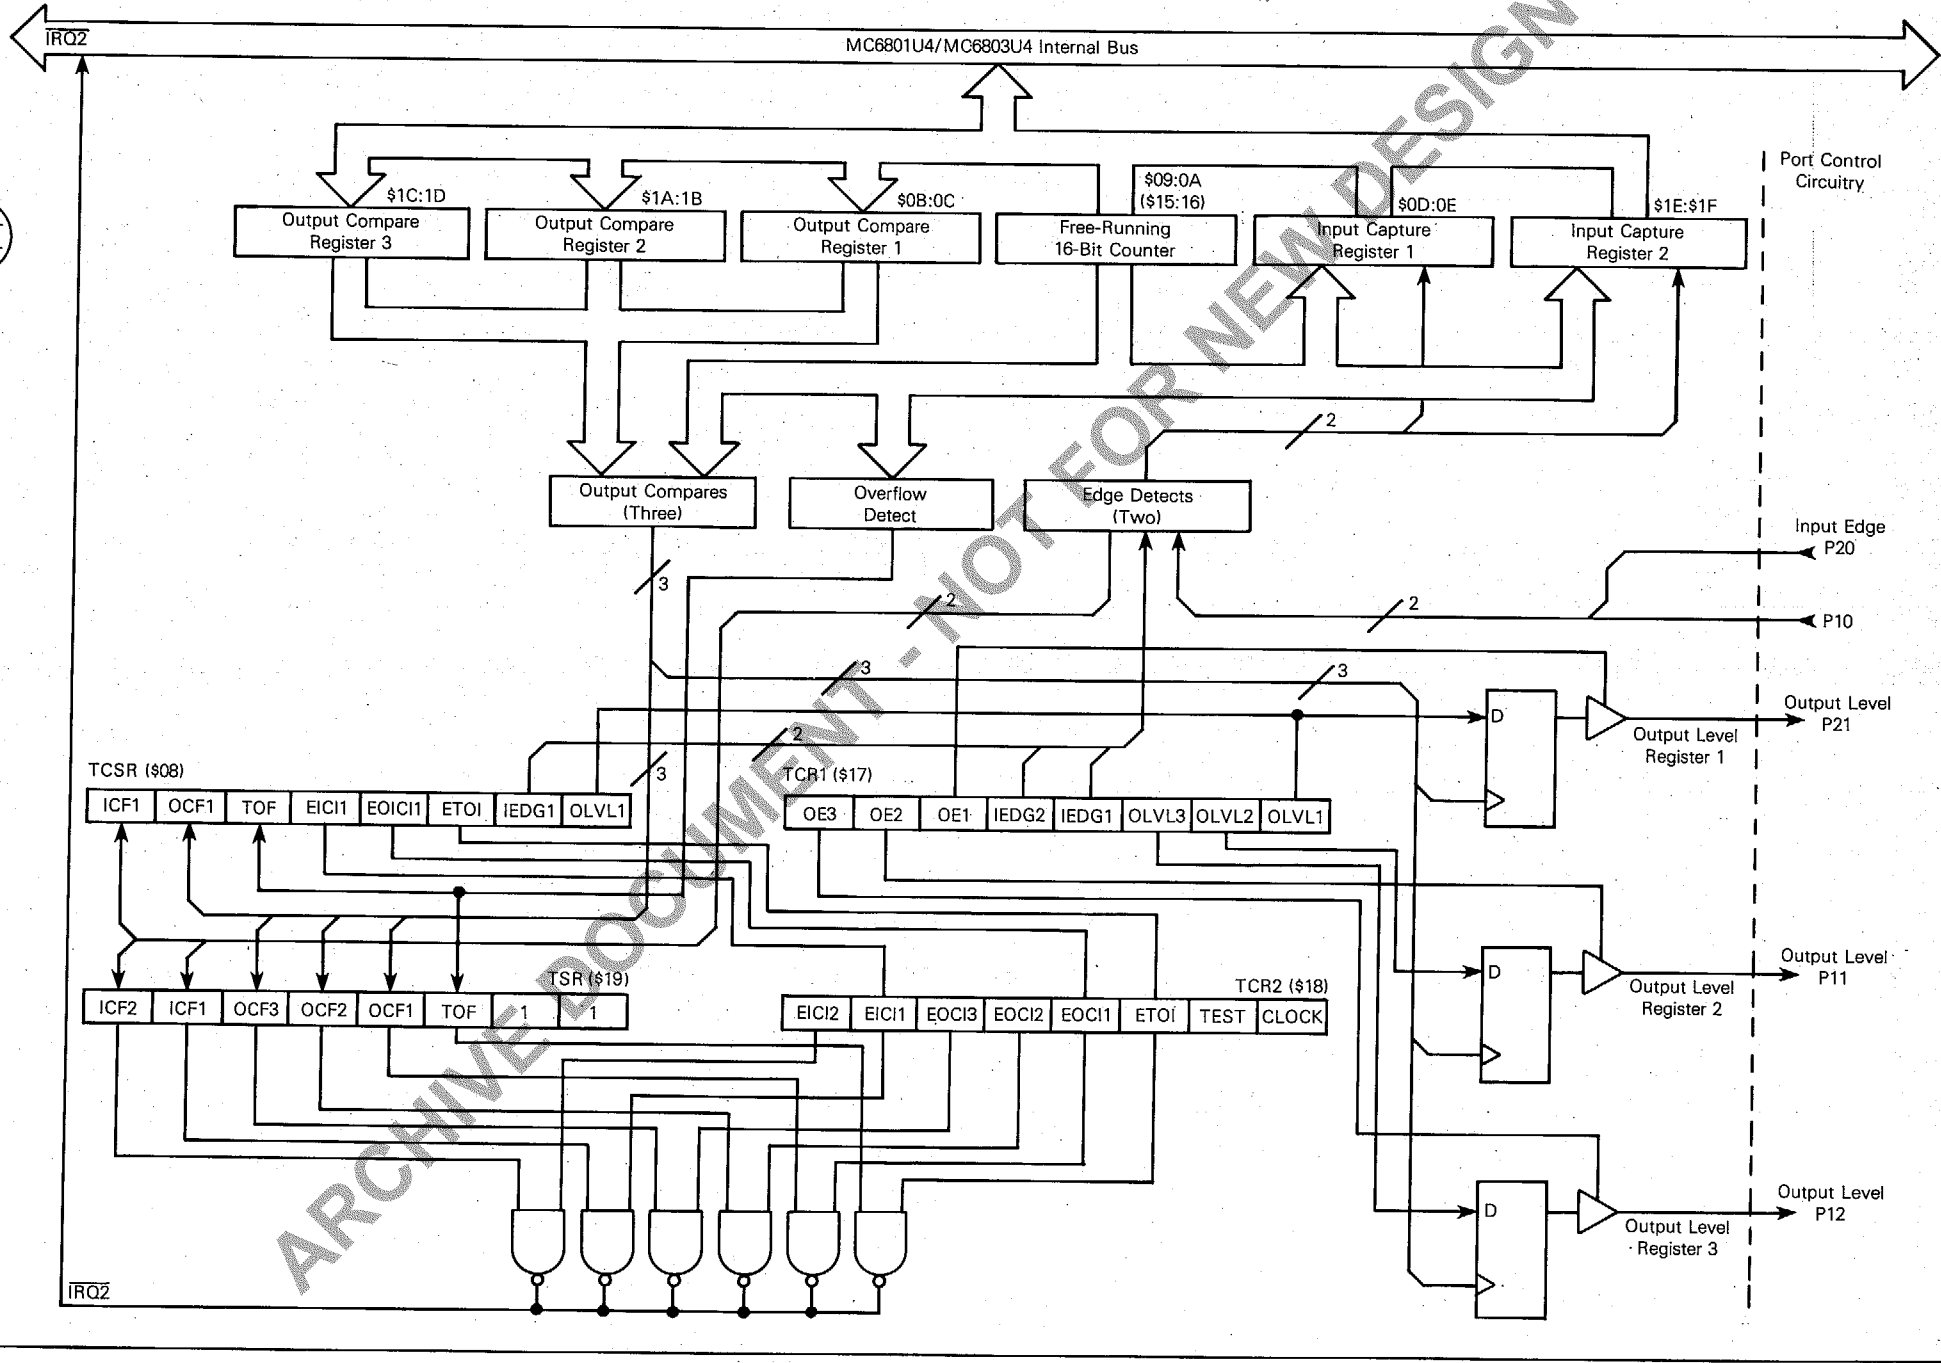

TIMER CONTROL AND STATUS REGISTERS

Four registers are used to provide the MC6801U4/MC6803U4 with control and status information about the three output compare functions, the timer overflow function, and the two input edge functions of the timer. They are:

- Timer Control and Status Register (TCSR)
- Timer Control Register 1 (TCR1)
- Timer Control Register 2 (TCR2)
- Timer Status Register (TSR)

FIGURE 21 — BLOCK DIAGRAM OF PROGRAMMABLE TIMER

ARCHIVED DOCUMENT - NOT FOR NEW DESIGN

TIMER CONTROL AND STATUS REGISTER (TCSR) (\$08) — The timer control and status register is an 8-bit register of which all bits are readable, while only bits 0-4 can be written. All the bits in this register are also accessible through the two timer control registers and the timer status register. The three most significant bits provide the timer status and indicate if:

1. a proper level transition has been detected at P20,
2. a match has occurred between the free-running counter and output compare register 1, or
3. the free-running counter has overflowed.

Each of the three events can generate an $\overline{IRO2}$ interrupt and is controlled by an individual enable bit in the TCSR.

TIMER CONTROL AND STATUS REGISTER							
7	6	5	4	3	2	1	0
ICF1	OCF1	TOF	EIC1	EOC1	ETOI	IEDG1	OLVL1

\$08

- Bit 0 Output Level 1** — OLVL1 is clocked to output level register 1 by a successful output compare and will appear at P21 if bit 1 of the port 2 data direction register is set and the OE1 control bit in timer control register 1 is set. OLVL1 and output level register 1 are cleared during reset. Refer to **TIMER CONTROL REGISTER 1 (TCR1) (\$17)**.
- Bit 1 Input Edge 1** — IEDG1 is cleared during reset and controls which level transition on P20 will trigger a counter transfer to input capture register 1:
 IEDG1=0 transfer on a negative-edge
 IEDG1=1 transfer on a positive-edge
 Refer to **TIMER CONTROL REGISTER 1 (TCR1) (\$17)**.
- Bit 2 Enable Timer Overflow Interrupt** — When set, an $\overline{IRO2}$ interrupt will be generated when the timer overflow flag is set; when clear, the interrupt is inhibited. ETOI is cleared during reset. Refer to **TIMER CONTROL REGISTER 2 (TCR2) (\$18)**.
- Bit 3 Enable Output Compare Interrupt 1** — When set, an $\overline{IRO2}$ interrupt will be generated when output compare flag 1 is set; when clear, the interrupt is inhibited. EOC1 is cleared during reset. Refer to **TIMER CONTROL REGISTER 2 (TCR2) (\$18)**.
- Bit 4 Enable Input Capture Interrupt 1** — When set, an $\overline{IRO2}$ interrupt will be generated when input capture flag 1 is set; when clear, the interrupt is inhibited. EIC1 is cleared during reset. Refer to **TIMER CONTROL REGISTER 2 (TCR2) (\$18)**.
- Bit 5 Timer Overflow Flag** — The TOF is set when the counter contains all ones (\$FFFF). It is cleared by reading the TCSR or the TSR (with TOF set) and the counter high byte (\$09), or during reset. Refer to **TIMER STATUS REGISTER (TSR) (\$19)**.
- Bit 6 Output Compare Flag 1** — OCF1 is set when output compare register 1 matches the free-running counter. OCF1 is cleared by reading the TCSR or the TSR (with OCF1 set) and then writing to output compare register 1 (\$0B or \$0C); or during reset. Refer to **TIMER STATUS REGISTER (TSR) (\$19)**.

- Bit 7 Input Capture Flag** — ICF1 is set to indicate that a proper level transition has occurred; it is cleared by reading the TCSR or the TSR (with ICF1 set) and the input capture register 1 high byte (\$0D), or during reset. Refer to **TIMER STATUS REGISTER (TSR) (\$19)**.

TIMER CONTROL REGISTER 1 (TCR1) (\$17) — Timer control register 1 is an 8-bit read/write register which contains the control bits for interfacing the output compare and input capture registers to the corresponding I/O pins.

TIMER CONTROL REGISTER 1							
7	6	5	4	3	2	1	0
OE3	OE2	OE1	IEDG2	IEDG1	OLVL3	OLVL2	OLVL1

\$17

- Bit 0 Output Level 1** — OLVL1 is clocked to output level register 1 by a successful output compare and will appear at P21 if bit 1 of the port 2 data direction register is set and the OE1 control bit is set. OLVL1 and output level register 1 are cleared during reset. Refer to **TIMER CONTROL AND STATUS REGISTER (TCSR) (\$08)**.
- Bit 1 Output Level 2** — OLVL2 is clocked to output level register 2 by a successful output compare and will appear at P11 if bit 1 of port 1 data direction register is set and the OE2 control bit is set. OLVL2 and output level register 2 are cleared during reset.
- Bit 2 Output Level 3** — OLVL3 is clocked to output level register 3 by a successful output compare and will appear at P12 if bit 2 of port 1 data direction register is set and the OE3 control bit is set. OLVL3 and output level register 3 are cleared during reset.
- Bit 3 Input Edge 1** — IEDG1 is cleared during reset and controls which level transition on P20 will trigger a counter transfer to input capture register 1.
 IEDG1=0 transfer on a negative-edge
 IEDG1=1 transfer on a positive-edge
 Refer to **TIMER CONTROL AND STATUS REGISTER (TCSR) (\$08)**.
- Bit 4 Input Edge 2** — IEDG2 is cleared during reset and controls which level transition on P10 will trigger a counter transfer to input capture register 2.
 IEDG2=0 transfer on a negative-edge
 IEDG2=1 transfer on a positive-edge
- Bit 5 Output Enable 1** — OE1 is set during reset and enables the contents of output level register 1 to be connected to P21 when bit 1 of port 2 data direction register is set.
 OE1=0 port 2 bit 1 data register output
 OE1=1 output level register 1
- Bit 6 Output Enable 2** — OE2 is cleared during reset and enables the contents of output level register 2 to be connected to P11 when bit 1 of port 1 data direction register is set.
 OE2=0 port 1 bit 1 data register output
 OE2=1 output level register 2

- Bit 7 **Output Enable 3** — OE3 is cleared during reset and enables the contents of output level register 3 to be connected to P12 when bit 2 of port 1 data direction register is set
 OE3=0 port 1 bit 2 data register output
 OE3=1 output level register 3

TIMER CONTROL REGISTER 2 (TCR2) (\$18) — Timer control register 2 is an 8-bit read/write register (except bits 0 and 1) which enable the interrupts associated with the free-running counter, the output compare registers, and the input capture registers. In test mode 0, two more bits (clock and test) are available for checking the timer.

**TIMER CONTROL REGISTER 2
(Non-Test Modes)**

7	6	5	4	3	2	1	0	
EIC2	EIC1	EOC3	EOC2	EOC1	ETOI	1	1	\$18

Bits 0-1 **Read-Only Bits** — When read, these bits return a value of 1. Refer to **TIMER CONTROL REGISTER 2 (Test Mode)**.

Bit 2 **Enable Timer Overflow Interrupt** — When set, an $\overline{IRQ2}$ interrupt will be generated when the timer overflow flag is set; when clear, the interrupt is inhibited. ETOI is cleared during reset. Refer to **TIMER CONTROL AND STATUS REGISTER (TCSR) (\$08)**.

Bit 3 **Enable Output Compare Interrupt 1** — When set, an $\overline{IRQ2}$ interrupt will be generated when the output compare flag 1 is set; when clear, the interrupt is inhibited. EOC1 is cleared during reset. Refer to **TIMER CONTROL AND STATUS REGISTER (TCSR) (\$08)**.

Bit 4 **Enable Output Compare Interrupt 2** — When set, an $\overline{IRQ2}$ interrupt will be generated when the output compare flag 2 is set; when clear, the interrupt is inhibited. EOC2 is cleared during reset.

Bit 5 **Enable Output Compare Interrupt 3** — When set, an $\overline{IRQ2}$ interrupt will be generated when the output compare flag 3 is set; when clear, the interrupt is inhibited. EOC3 is cleared during reset.

Bit 6 **Enable Input Capture Interrupt 1** — When set, an $\overline{IRQ2}$ interrupt will be generated when the input capture flag 1 is set; when clear, the interrupt is inhibited. EIC1 is cleared during reset. Refer to **TIMER CONTROL AND STATUS REGISTER (TCSR) (\$08)**.

Bit 7 **Enable Input Capture Interrupt 2** — When set, an $\overline{IRQ2}$ interrupt will be generated when the input capture flag 2 is set; when clear, the interrupt is inhibited. EIC2 is cleared during reset.

The timer test bits (test and clock) allow the free-running counter to be tested as two separate 8-bit counters to speed testing.

**TIMER CONTROL REGISTER 2
(Test Mode)**

7	6	5	4	3	2	1	0	
EIC2	EIC1	EOC3	EOC2	EOC1	ETOI	TEST	CLOCK	\$18

Bit 0 **CLOCK** — The CLOCK control bit selects which half of the 16-bit free-running counter (MSB or LSB) should be clocked with E. The CLOCK bit is a read/write bit only in mode 0 and is set during reset.

CLOCK=0 — Only the eight most significant bits of the free-running counter run with TEST=0.

CLOCK=1 — Only the eight least significant bits of the free-running counter run when TEST=0.

Bit 1 **TEST** — the TEST control bit enables the timer test mode. TEST is a read/write bit in mode 0 and is set during reset.

TEST=0 — Timer test mode enabled:

a) The timer LSB latch is transparent which allows the LSB to be read independently of the MSB.

b) Either the MSB or the LSB of the timer is clocked by E, as defined by the CLOCK bit.

TEST=1 — Timer test mode disabled.

Bits 2-7 See **TIMER CONTROL REGISTER 2 (Non-Test Modes)**. (These bits function the same as in the non-test modes.)

TIMER STATUS REGISTER (TSR) (\$19) — The timer status register is an 8-bit read-only register which contains the flags associated with the free-running counter, the output compare registers, and the input capture registers.

TIMER STATUS REGISTER

7	6	5	4	3	2	1	0	
ICF2	ICF1	OCF3	OCF2	OCF1	TOF	1	1	\$19

Bits 0-1 Not used.

Bit 2 **Timer Overflow Flag** — The TOF is set when the counter contains all ones (\$FFFF). It is cleared by reading the TSR or the TCSR (with TOF set) and then the counter high byte (\$09), or during reset. Refer to **TIMER CONTROL AND STATUS REGISTER (TCSR) (\$08)**.

Bit 3 **Output Compare Flag 1** — OCF1 is set when output compare register 1 matches the free-running counter. OCF1 is cleared by reading the TSR or the TCSR (with OCF1 set) and then writing to output compare register 1 (\$0B or \$0C), or during reset. Refer to **TIMER CONTROL AND STATUS REGISTER (TCSR) (\$08)**.

Bit 4 **Output Compare Flag 2** — OCF2 is set when output compare register 2 matches the free-running counter. OCF2 is cleared by reading the TSR (with OCF2 set) and then writing to output compare register 2 (\$1A or \$1B), or during reset.

Bit 5 **Output Compare Flag 3** — OCF3 is set when output compare register 3 matches the free-running counter. OCF3 is cleared by reading the TSR (with OCF3 set) and then writing to output compare register 3 (\$1C or \$1D), or during reset.

Bit 6 **Input Capture Flag 1** — ICF1 is set to indicate that a proper level transition has occurred; it is cleared by reading the TSR or the TCSR (with ICF1 set) and the input capture register 1 high byte (\$0D), or during reset. Refer to **TIMER CONTROL AND STATUS REGISTER (TCSR) (\$08)**.

Bit 7 **Input Capture Flag 2** — ICF2 is set to indicate that a proper level transition has occurred; it is cleared by reading the TSR (with ICF2 set) and the input capture register 2 high byte (\$1E), or during reset.

SERIAL COMMUNICATIONS INTERFACE

A full-duplex asynchronous serial communications interface (SCI) is provided with two data formats and a variety of rates. The SCI transmitter and receiver are functionally independent but use the same data format and bit rate. Serial data formats include standard mark/space (NRZ) and bi-phase and both provide one start bit, eight data bits, and one stop bit. "Baud" and "bit rate" are used synonymously in the following description.

WAKE-UP FEATURE

In a typical serial loop multiprocessor configuration, the software protocol will usually identify the addressee(s) at the beginning of the message. In order to permit uninterested MPUs to ignore the remainder of the message, wake-up feature is included whereby all further SCI receiver flag (and interrupt) processing can be inhibited until its data line goes idle. An SCI receiver is re-enabled by an idle string of ten consecutive ones or during reset. Software must provide for

the required idle string between consecutive messages and prevent it within messages.

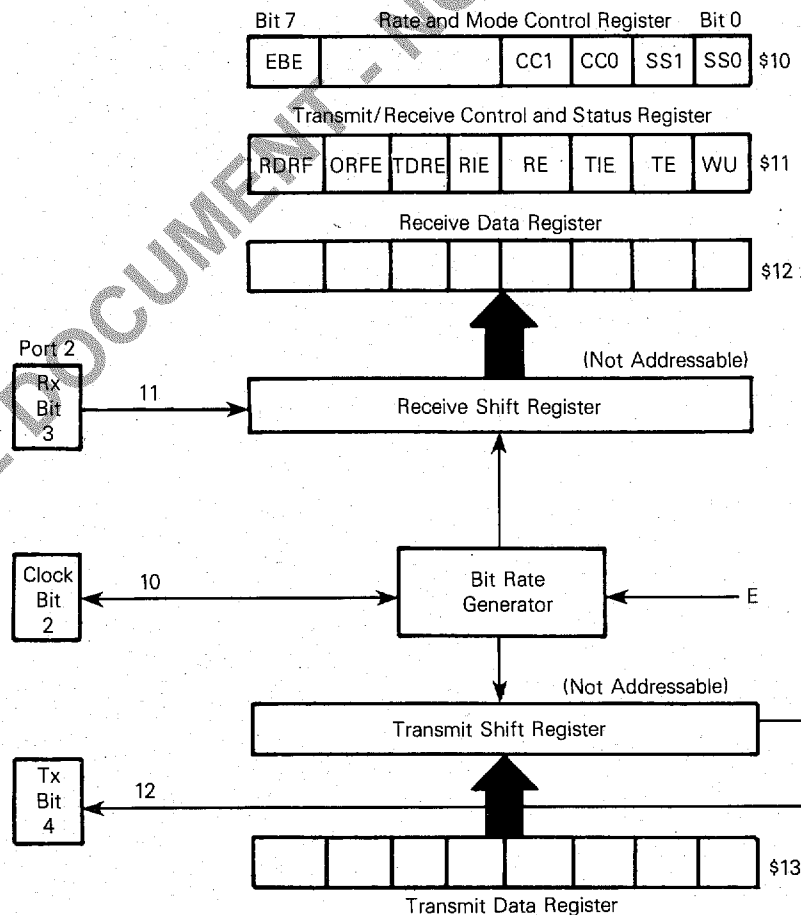

PROGRAMMABLE OPTIONS

- The following features of the SCI are programmable:
- Format: standard mark/space (NRZ) or bi-phase
 - Clock: external or internal bit rate clock
 - Baud: one of eight per E clock frequency or external clock ($\times 8$ desired baud)
 - Wake-Up Feature: enabled or disabled
 - Interrupt Requests: enabled individually for transmitter and receiver
 - Clock Output: internal bit rate clock enabled or disabled to P22

SERIAL COMMUNICATIONS REGISTERS

The serial communications interface includes four addressable registers as depicted in Figure 22. It is controlled by the rate and mode control register and the transmit/receive control and status register. Data is transmitted and received utilizing a write-only transmit register and a read-only receive register. The shift registers are not accessible to software.

FIGURE 22 — SCI REGISTERS

RATE AND MODE CONTROL REGISTER (RMCR) (\$10)

— The rate and mode control register controls the SCI rate, format, clock source, and under certain conditions, the configuration of P22. The register consists of five write-only bits which are cleared during reset. The two least significant bits in conjunction with bit 7 control the bit rate of the internal clock and the remaining two bits control the format and clock source.

RATE AND MODE CONTROL REGISTER

7	6	5	4	3	2	1	0	
EBE	X	X	X	CC1	CC0	SS1	SS0	\$10

Bit 1:Bit 0 SS1:SS0 Speed Select — These two bits select the baud when using the internal clock. Eight rates may be selected (in conjunction with bit 7) which are a function of the MCU input frequency. Table 6 lists bit time and rates for three selected MCU frequencies.

Bit 3:Bit 2 CC1:CC0 Clock Control and Format Select — These two bits control the format and select the serial clock source. If CC1 is set, the DDR value

for P22 is forced to the complement of CC0 and cannot be altered until CC1 is cleared. If CC1 is cleared after having been set, its DDR value is unchanged. Table 7 defines the formats, clock source, and use of P22.

Bits 4-6

Not used.

Bit 7

EBE Enhanced Baud Enable — EBE selects the standard MC6801 baud rates when clear and the additional baud rates when set (Table 6). This bit is cleared by reset and is a write-only control bit.

EBE=0 standard MC6801 baud rates

EBE=1 additional baud rates

If both CC1 and CC0 are set, an external TTL-compatible clock must be connected to P22 at eight times (8x) the desired bit rate, but not greater than E, with a duty cycle of 50% (±10%). If CC1:CC0=10, the internal bit rate clock is provided at P22 regardless of the values for TE or RE.

NOTE

The source of SCI internal bit rate clock is the timer free-running counter. An MPU write to the counter in mode 0 can disturb serial operations.

TABLE 6 — SCI BIT TIMES AND RATES

EBE	SS1:SS0		4 f ₀ →	2.4576 MHz		4.0 MHz		4.9152 MHz

TABLE 7 — SCI FORMAT AND CLOCK SOURCE CONTROL

CC1:CC0	Format	Clock Source	Port 2 Bit 2
00	Bi-Phase	Internal	Not Used
01	NRZ	Internal	Not Used
10	NRZ	Internal	Output
11	NRZ	External	Input

TRANSMIT/RECEIVE CONTROL AND STATUS REGISTER (TRCSR) (\$11) — The transmit/receive control and status register controls the transmitter, receiver, wake-up feature, and two individual interrupts, and monitors the status of serial operations. All eight bits are readable while bits 0 to 4 are also writable. The register is initialized to \$20 by **RESET**.

TRANSMIT/RECEIVE CONTROL AND STATUS REGISTER

7	6	5	4	3	2	1	0
RDRF	ORFE	TDRE	RIE	RE	TIE	TE	WU

- Bit 0 **“Wake-Up” on Idle Line** — When set, WU enables the wake-up function; it is cleared by ten consecutive ones or during reset. WU will not be set if the line is idle. Refer to **WAKE-UP FEATURE**.
- Bit 1 **Transmit Enable** — When set, P24 DDR bit is set, cannot be changed, and will remain set if TE is subsequently cleared. When TE is changed from clear to set, the transmitter is connected to P24 and a preamble of nine consecutive ones is transmitted. TE is cleared during reset.
- Bit 2 **Transmit Interrupt Enable** — When set, an $\overline{\text{IRQ2}}$ is set; when clear, the interrupt is inhibited. TE is cleared during reset.
- Bit 3 **Receive Enable** — When set, the P23 DDR bit is cleared, cannot be changed, and will remain clear if RE is subsequently cleared. While RE is set, the SCI receiver is enabled. RE is cleared during reset.
- Bit 4 **Receiver Interrupt Enable** — When set, an $\overline{\text{IRQ2}}$ interrupt is enabled when RDRF and/or ORFE is set; when clear, the interrupt is inhibited. RIE is cleared during reset.
- Bit 5 **Transmit Data Register Empty** — TDRE is set when the transmit data register is transferred to the output serial shift register or during reset. It is cleared by reading the TRCSR (with TDRE set) and then writing to the transmit data register. Additional data will be transmitted only if TDRE has been cleared.

Bit 6 **Overrun Framing Error** — If set, ORFE indicates either an overrun or framing error. An overrun is a new byte ready to transfer to the receiver data register with RDRF still set. A receiver framing error has occurred when the byte boundaries of the bit stream are not synchronized to the bit counter. An overrun can be distinguished from a framing error by the state of RDRF: if RDRF is set, then an overrun has occurred; otherwise, a framing error has been detected. Data is not transferred to the receive data register in an overrun condition. Unframed data causing a framing error is transferred to the receive data register. However, subsequent data transfer is blocked until the framing error flag is cleared. ORFE is cleared by reading the TRCSR (with ORFE set) then the receive data register, or during reset.

Bit 7 **Receive Data Register Full** — RDRF is set when the input serial shift register is transferred to the receive data register, or during reset.

SERIAL OPERATIONS

The SCI is initialized by writing control bytes first to the rate and mode control register and then to the transmit/receive control and status register. When TE is set, the output of the transmit serial shift register is connected to P24 and serial output is initiated by transmitting a 9-bit preamble of ones.

At this point, one of two situations exists: 1) if the transmit data register is empty (TDRE=1), a continuous string of ones will be sent indicating an idle line; or 2) if a byte has been written to the transmit data register (TDRE=0), it will be transferred to the output serial shift register (synchronized with the bit rate clock), TDRE will be set, and transmission will begin.

The start bit (0), eight data bits (beginning with bit 0), and a stop bit (1) will be transmitted. If TDRE is still set when the next byte transfer occurs, ones will be sent until more data is provided. In bi-phase format, the output toggles at the start of each bit and at half-bit time when a one is sent. Receive operation is controlled by RE which configures P23 as an input and enables the receiver. SCI data formats are illustrated in Figure 23.

FIGURE 23 — SCI DATA FORMATS

INSTRUCTION SET

The MC6801U4/MC6803U4 is directly source compatible with the MC6801 and upward source and object code compatible with the MC6800. Execution times of key instructions have been reduced and several instructions have been added, including a hardware multiply. A list of new operations added to the MC6800 instruction set is shown in Table 1.

In addition, two special opcodes, 4E and 5E, are provided for test purposes. These opcodes force the program counter

to increment like a 16-bit counter causing address lines used in the expanded modes to increment until the device is reset. These opcodes have no mnemonics.

The coding of the first (or only) byte corresponding to an executable instruction is sufficient to identify the instruction and the addressing mode. The hexadecimal equivalents of the binary codes, which result from the translation of the 82 instructions in all valid modes of addressing, are shown in Table 8. There are 220 valid machine codes, 34 unassigned codes, and 2 codes reserved for test purposes.

 INHER ≡ Inherent INDXD ≡ Indexed IMMED ≡ Immediate
 REL ≡ Relative EXTND ≡ Extended DIR ≡ Direct
- Unassigned opcodes are indicated by "•" and should not be executed.
- Codes marked by "T" force the PC to function as a 16-bit counter.

PROGRAMMING MODEL

A programming model for the MC6801U4/MC6803U4 is shown in Figure 8. Accumulator A can be concatenated with accumulator B and jointly referred to as accumulator D where A is the most significant byte. Any operation which modifies the double accumulator will also modify accumulators A and/or B. Other registers are defined as follows:

PROGRAM COUNTER — The program counter is a 16-bit register which always points to the next instruction.

STACK POINTER — The stack pointer is a 16-bit register which contains the address of the next available location in a pushdown/pullup (LIFO) queue. The stack resides in random-access memory at a location defined by the programmer.

INDEX REGISTER — The index register is a 16-bit register which can be used to store data or provide an address for the indexed mode of addressing.

ACCUMULATORS — The MPU contains two 8-bit accumulators, A and B, which are used to store operands and results from the arithmetic logic unit (ALU). They can also be concatenated and referred to as the D (double) accumulator.

CONDITION CODE REGISTER — The condition code register indicates the results of an instruction and includes the following five condition bits: negative (N), zero (Z), overflow (V), carry/borrow from MSB (C), and half carry from bit 3 (H). These bits are testable by the conditional branch instructions. Bit 4 is the interrupt mask (I bit) and inhibits all maskable interrupts when set. The two unused bits, B6 and B7, are read as ones.

ADDRESSING MODES

Six addressing modes can be used to reference memory. A summary of addressing modes for all instructions is presented in Tables 9, 10, 11, and 12 where execution times are provided in E cycles. Instruction execution times are summarized in Table 13. With an input frequency of 4 MHz, one E cycle is equivalent to one microsecond. A cycle-by-cycle description of bus activity for each instruction is provided in Table 14 and descriptions of selected instructions are shown in Figure 24.

IMMEDIATE ADDRESSING — The operand or "immediate byte(s)" is contained in the following byte(s) of the

instruction where the number of bytes matches the size of the register. These are two or three byte instructions.

DIRECT ADDRESSING — The least significant byte of the operand address is contained in the second byte of the instruction and the most significant byte is assumed to be \$00. Direct addressing allows the user to access \$00 through \$FF using two byte instructions and execution time is reduced by eliminating the additional memory access. In most applications, the 256-byte area is reserved for frequently referenced data.

EXTENDED ADDRESSING — The second and third bytes of the instruction contain the absolute address of the operand. These are three byte instructions.

INDEXED ADDRESSING — The unsigned offset contained in the second byte of the instruction is added with carry to the index register and is used to reference memory without changing the index register. These are two byte instructions.

INHERENT ADDRESSING — The operand(s) is a register and no memory reference is required. These are single byte instructions.

RELATIVE ADDRESSING — Relative addressing is used only for branch instructions. If the branch condition is true, the program counter is overwritten with the sum of a signed single byte displacement in the second byte of the instruction and the current program counter. This provides a branch range of -126 to $+129$ bytes from the first byte of the instruction. These are two byte instructions.

SUMMARY OF CYCLE-BY-CYCLE OPERATION

Table 14 provides a detailed description of the information present on the address bus, data bus, and the read/write (R/W) line during each cycle of each instruction.

The information is useful in comparing actual with expected results during debug of both software and hardware as the program is executed. The information is categorized in groups according to addressing mode and number of cycles per instruction. In general, instructions with the same addressing mode and number of cycles execute in the same manner. Exceptions are indicated in the table.

Note that during MPU reads of internal locations, the resultant value will not appear on the external data bus except in mode 0. "High order" byte refers to the most significant byte of a 16-bit value.

FIGURE 24 — SPECIAL OPERATIONS

JSR, Jump to Subroutine

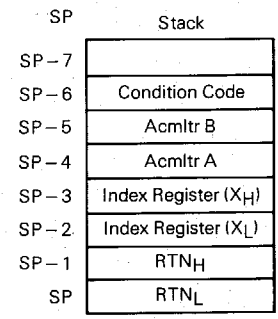

BSR, Branch To Subroutine

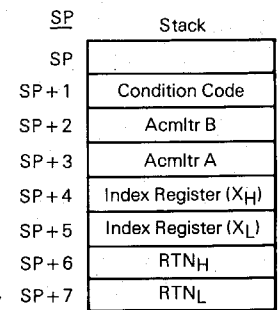

RTS, Return from Subroutine

SWI, Software Interrupt

WAI, Wait for Interrupt

RTI, Return from Interrupt

JMP, Jump

Legend:
 RTN = Address of next instruction in Main Program to be executed upon return from subroutine
 RTN_H = Most significant byte of Return Address
 RTN_L = Least significant byte of Return Address
 → = Stack Pointer After Execution
 K = 8-bit Unsigned Value

ARCHIVE DOCUMENT - NOT FOR NEW DESIGN

**APPENDIX
CUSTOM MC6801U4 ORDERING INFORMATION**

(\$F000-\$FFFF). See Figure A-1 for recommended marking procedure.

A.1 CUSTOM MC6801U4 ORDERING INFORMATION

The custom MC6801U4 specifications may be transmitted to Motorola in any of the following media:

- 1) EPROMs
- 2) MDOS diskette

The specification should be formatted and packed, as indicated in the appropriate paragraph below, and mailed prepaid and insured with a cover letter (see Figure A-2) to:

Motorola Inc.
3501 Ed Bluestein Blvd.
Austin, Texas 78721
Mail Drop L-13

A copy of the cover letter should also be mailed separately.

A.2 EPROMs

MCM2708 and MCM2716 type EPROMs, programmed with the custom program (positive logic sense for address and data), may be submitted for pattern generation. Both the MCM2708s and MCM2716s must be clearly marked to indicate which PROM corresponds to which address space.

EXORciser is a registered trademark of Motorola Inc.
UNICORN is a trademark of Motorola Inc.

FIGURE A-1

XXX = Customer ID

After the EPROMs are marked, they could be placed in a conductive IC carrier and securely packed. Do not use styrofoam.

A.3 DISKETTE (MDOS)

The start/end location should be written on the label using EXORciser format.

MC6801U4L1 UNICORN Monitor

An MC6801U4 may be purchased without specifying the ROM pattern. This standard part is labeled as MC6801U4L1 and contains a 2K monitor (UNICORN) in the ROM. This monitor may be used to evaluate and debug a program under development. Details and a source listing are specified in the *UNICORN Monitor Reference Manual M68UNICORN(D1)*.
